Coding Conventions

Due to this being a collaborative software project among new developers, it's important to make sure that the code you write is clean and usable by others. We predominantly use two languages in this project, C++ and Python. Below are a list of coding conventions for each respective language in the project. There may be exceptions to these rules, but otherwise they should be followed. A code linter will be created to ensure that code conforms to there standards.

**roslint**

To check if you code passes standard checks, compile using:

```
rsmake roslint
```

This will invoke the compiler with the code linter turned on. The C++ linter will run first and will fail with an error if the linter fails and the Python linter will not be run. If the C++ code passes the linter then the Python linter will be run.

**All Languages**

**Indentation**

Spaces shall be used for indentation, no tabs.

**Rational:** mixing tabs and spaces can cause major bugs in Python, and can create ugly formatted code in all other languages, so consistency is important. Although I prefer all tabs in Python, spaces makes more sense for other languages.

**Line Length**

The maximum length of a line shall be 80 characters

**Rational:** this results in code that is readable on most screens without wrapping lines

**Trailing Spaces**

Trailing whitespace at the end of a line is not allowed.

**Rational:** most text editors will actually automatically chop the trailing whitespace when you open a file. If people aren't paying attention, this can result in them committing a file where they made no functional changes other than to cut the whitespace, resulting in a confusing source control history. In addition, it's just a cleanliness thing.
Extra Newlines

More than one blank line in a row is not allowed. **Rational:** If you need to break up your code into logical chunks it is better to use a single newline and a comment describing the next code block.

**C++**

running

```bash
astyle -A1 -N -n <file name>
```

on your C++ files should clean them up nicely.

**Python**

Nodes should be defined in classes with the constructor called in the “main” section.

```python
def Node():
    def __init__():
        # define pubs and subs here
        ...
    
    if __name__ == '__main__':
        rospy.init_node()
        Node()
        rospy.spin()
```
